Team

Introduction

The typed
lambda
calculus

Type checking

Type inference

F# basic
types

Named types

Conclusion

Appendix

Idea

This makes the lambda calculus safer to compose, as we run no more the risk of passing a parameter of the wrong shape (like an integer where a function is expected)

The typed lambda calculus

Types,
inference, and
F# data types

The
INFDEV@HR
Team

Introduction

The typed
lambda
calculus

Type checking

Type inference

F# basic
types

Named types

Conclusion

Appendix

Types in the lambda calculus follow the same basic syntactic shape of the lambda calculus itself.

Consider any type τ ; it will be made up, recursively, out of any of the following shapes:

- a type variable (like generic type parameters, such as T): α
- a generic type definition (like the definition of `List<T>`):
 $\forall \alpha \Rightarrow \tau$
- a function type: $\tau \rightarrow \tau$
- a type application (like `List<Customer>`): $\tau \tau$

INFDEV@HR
Team

Introduction

The typed
lambda
calculus

Type checking

Type inference

F# basic
types

Named types

Conclusion

Appendix

Lambda calculus programs are now extended to include type declarations:

Consider any term t ; it will be made up, recursively, out of any of the following shapes:

- a free variable: x
- a lambda definition: $\lambda x \rightarrow t$
- a generic parameter introduction: $\Lambda \alpha \Rightarrow t$
- a value application: $t \ t$
- a type application: $t \ \tau$

The typed lambda calculus

Types,
inference, and
F# data types

The
INFDEV@HR
Team

Introduction

The typed
lambda
calculus

Type checking

Type inference

F# basic
types

Named types

Conclusion

Appendix

True and false now become generic with respect to the inputs t and f :

$$\Lambda\alpha \Rightarrow (\lambda (t : \alpha) \ (f : \alpha) \rightarrow t)$$

$$\Lambda\alpha \Rightarrow (\lambda (t : \alpha) \ (f : \alpha) \rightarrow f)$$

The typed lambda calculus

Types,
inference, and
F# data types

The
INFDEV@HR
Team

Introduction

The typed
lambda
calculus

Type checking

Type inference

F# basic
types

Named types

Conclusion

Appendix

Numbers now become generic with respect to the data manipulated through z and s :

$$\Lambda\alpha \Rightarrow (\lambda (s : (\alpha \rightarrow \alpha)) \ (z : \alpha) \rightarrow z)$$

$$\Lambda\alpha \Rightarrow (\lambda (s : (\alpha \rightarrow \alpha)) \ (z : \alpha) \rightarrow (s \ (s \ z)))$$

Typed pairs

- A pair takes as input the two values, x and y
- It then expects a function, g , which will consume x and y and produce some final result
- x and y have generic types, α and β
- g also has generic type, it takes as input an α and a β , and returns a γ

The typed lambda calculus

Types,
inference, and
F# data types

The
INFDEV@HR
Team

Introduction

The typed
lambda
calculus

Type checking

Type inference

F# basic
types

Named types

Conclusion

Appendix

Pairs become generic with respect to the types of the input, but also the generated output:

$$\Lambda\alpha \Rightarrow \Lambda\beta \Rightarrow (\lambda(x:\alpha) \ (y:\beta) \rightarrow \Lambda\gamma \Rightarrow (\lambda(f:(\alpha \rightarrow \beta \rightarrow \gamma)) \rightarrow ((f\ x)\ y))))$$

Types,
inference, and
F# data types

The
INFDEV@HR
Team

Introduction

The typed
lambda
calculus

Type checking

Type inference

F# basic
types

Named types

Conclusion

Appendix

Pairs become generic with respect to the types of the input,
but also the generated output:

$$\Lambda\alpha\Rightarrow\Lambda\beta\Rightarrow(\lambda(p:(\alpha\times\beta))\rightarrow((p\ \alpha)\ (\lambda(x:\alpha)\ (y:\beta)\rightarrow x))))$$

$$\Lambda\alpha\Rightarrow\Lambda\beta\Rightarrow(\lambda(p:(\alpha\times\beta))\rightarrow((p\ \beta)\ (\lambda(x:\alpha)\ (y:\beta)\rightarrow y))))$$

Typed union

- A union is built from one of two possible values, x and y
- It then expects two functions, f and g , which will consume x or y and produce some final result
- x and y have generic types, α and β
- f and g also have generic types, they takes as input an α or a β , but both return a γ

Introduction

The typed
lambda
calculus

Type checking

Type inference

F# basic
types

Named types

Conclusion

Appendix

Thanks to types, we can now verify that terms are well-composed: this can prevent various forms of bugs

- Passing an argument to a variable that is not a function
- Adding an integer and a list
- Performing the logical or between lists and trees
- Performing the logical and between functions
- ...

- This verification is called type-checking
- We perform a fake execution of a term, making sure that all function applications are matching
- As we go, we replace parts of the term with its type
- When the whole term has been replaced with its type, we know the return type of the original program
- If the process gets stuck somewhere, we stop and give back an error^a

^ausually a compiler error

Types,
inference, and

Introduction

The typed
lambda
calculus

Type checking

Type inference

F# basic
types

Named types

Conclusion

Appendix

Is a term well-typed

Type checking uses a series of typing rules that look a bit like execution rules.

Types,
inference, and
F# data types

The
INFDEV@HR
Team

Introduction

The typed
lambda
calculus

Type checking

Type inference

F# basic
types

Named types

Conclusion

Appendix

When we encounter a variable, we simply return its type from Γ , which contains all variable declarations found so far

$$\frac{x : \sigma \in \Gamma}{\Gamma \vdash x : \sigma}$$

When we encounter a function declaration, we simply add the type of the parameter to Γ , and type check the function body

$$\frac{\Gamma, x : \sigma \vdash t : \tau}{\Gamma \vdash (\lambda x : \sigma \rightarrow t) : (\sigma \rightarrow \tau)}$$

Types,
inference, and
F# data types

The
INFDEV@HR
Team

Introduction

The typed
lambda
calculus

Type checking

Type inference

F# basic
types

Named types

Conclusion

Appendix

When we encounter a function application, we simply make sure that the input of the function has the same type as the parameter

$$\frac{\Gamma \vdash t : \sigma \rightarrow \tau \quad \Gamma \vdash u : \sigma}{\Gamma \vdash (t \ u) : \tau}$$

Type inference

F# basic
types

Named types

Conclusion

Appendix

Are type annotations necessary?

- Type annotations are not strictly necessary
- This means that, even if there are types, we might not need to write them all down
- Modern functional programming languages, like F#, Haskell, and Scala, are capable of guessing the types autonomously
- This is called type inference

Types,
inference, and
F# data types

The
INFDEV@HR
Team

Introduction

The typed
lambda
calculus

Type checking

Type inference

F# basic
types

Named types

Conclusion

Appendix

Are type annotations pointless?

- Type annotations are still useful at times
- This means that, even if there is type inference, sometimes we write the types explicitly
- Type inference might sometimes fail, so type annotations might solve the issue
- Type annotations act as documentation, and make complex code clearer

Introduction

The typed
lambda
calculus

Type checking

Type inference

F# basic
types

Named types

Conclusion

Appendix

Types in F# are exactly the same as those in the lambda calculus:

- the empty type `Unit`, with its only value `()`
- primitive machine types, such as `int`, `bool`, `string`, etc.
- type variable, which instead of greek letters such as α have an apostrophe as prefix: `'a`
- function types: `t → t`
- tuples, in the form: `'a * 'b`
- discriminated unions, in the form: `Choice<'a, 'b>`

INFDEV@HR
Team

Introduction

The typed
lambda
calculus

Type checking

Type inference

F# basic
types

Named types

Conclusion

Appendix

Type declarations in F# are the same as those in the lambda calculus.

An identifier, a colon, and a type:

```
(fun (x:int) -> (x + 1))
```

The same applies to let bindings:

```
let (x:int) = 0  
(x + 1)
```

Pairs (and tuples of size greater than two^a) are similarly handled:

^aThose can be matched, or extracted with `let (x,y,z,...) = t`

```
(fun (p:(int*bool)) -> ((fst p) + 1))
```

Types,
inference, and
F# data types

The
INFDEV@HR
Team

Introduction

The typed
lambda
calculus

Type checking

Type inference

F# basic
types

Named types

Conclusion

Appendix

Discriminated unions are also no surprise:

```
(fun (p:Choice<int,bool>) ->  
  match p with  
  | Choice10f2 x ->  
    (x + 1)  
  | Choice20f2 y ->  
    0  
)
```

Of course nothing stops us from using function types:

```
let (f:(int -> int)) =  
    fun (x:int) -> (x + 1)  
(f 2)
```

Type inference

F# basic
types

Named types

Conclusion

Appendix

We can use the `type` keyword to give a name to a type, for ease of later use:

```
type MyInt = int
let (f:(MyInt -> MyInt)) =
    fun (x:MyInt) -> (x + 1)
(f 2)
```

This makes the most sense when the name of the type is a tad longer^a:

^aRemember that a type might contain as many arrows, tuples, etc. as we might want!

```
type Int2 = (int -> int)
let (f:Int2) =
    fun (x:int) -> (x + 1)
(f 2)
```

Demo

Another short demo might be in order

Custom named types

- Sometimes existing type definitions are not clear or readable enough.
- For example, it is hard to guess that a long tuple like `string * string * int * int` actually represents a person
- Similarly, it is hard to guess that a long union like `Choice<Choice<int,int>, Choice<int, int>>` actually represents card and suit (hearts, diamonds, clubs, spades)

Custom named types

- The `type` keyword can define brand new types.
- These new types can have additional structure and internal names.
- The new types are substantially identical to (nested) tuples and (nested) unions.
- The only difference is that the elements of the tuple and the cases of the union can be augmented with a mnemonic name.

Named types

Conclusion

Appendix

Records

- Tuples with named elements are called **records**.
- They are declared between curly brackets.
- Each field of the record has a name, followed by a colon and the type of the field.

Team

Introduction

The typed
lambda
calculus

Type checking

Type inference

F# basic
types

Named types

Conclusion

Appendix

We can initialise a record with the values of the fields between curly brackets, each bound to the proper field name

```
type Person = { Name:string; Surname:string }  
let (p:Person) = { Name = "Haskell"; Surname =  
    "Curry" }  
( )
```

Introduction

The typed
lambda
calculus

Type checking

Type inference

F# basic
types

Named types

Conclusion

Appendix

We can access a record fields with the usual dot notation coming from C-style languages:

```
type Person = { Name:string; Surname:string }  
let (p:Person) = { Name = "Haskell"; Surname =  
    "Curry" }  
p.Name
```

We can modify large parts of a record fields with the `with` operator, which copies over all fields besides those explicitly specified:

```
type Person = { Name:string; Surname:string }  
let (p:Person) = { Name = "Haskell"; Surname =  
    "Curry" }  
{ p with Name = "F\#" }
```

Records

- Unions with named cases are called **discriminated unions**.
- They are declared as a series of constructors, each with its own parameters.
- Matching is the only way to access the data inside the instance of the discriminated union.

types

Named types

Conclusion

Appendix

An example record declaration for a widget size could look like:

```
type Size =  
    | Small  
    | Large  
    | Custom of Nat  
( )
```

We can initialise a union with the values of a constructor between brackets, of no argument at all for parameterless constructors

```
type Size =  
    | Small  
    | Large  
    | Custom of Nat  
let (s1:Size) = Small  
let (s2:Size) = (Custom 10)  
( )
```

calculus

Type checking

Type inference

F# basic
types

Named types

Conclusion

Appendix

A very important data structure in functional languages is the list.

In F# it is predefined^a as union of the empty list and the non-empty constructor:

^aSo you do not need to define it yourself!

```
type List<'a> =  
    | []  
    | (::) of 'a * List<'a>  
let (l1:List<int>) = []  
let (l2:List<int>) =  
    1 :: 2 :: 3 :: []  
( )
```

The
INFDEV@HR
Team

Introduction

The typed
lambda
calculus

Type checking

Type inference

F# basic
types

Named types

Conclusion

Appendix

We could recursively perform all sorts of operations on lists with simple matching.

Fortunately, we can make use of many of the existing available functions on lists:

- `map`, which transforms all elements of a list according to a specific transformation function
- `filter`, which removes some elements of a list according to a specific predicate function
- `reduce`, which collapses a list onto a single value according to a specific aggregation function
- `fold`, which collapses a list onto a single value according to a specific aggregation function and a starting aggregate value

calculus

Type checking

Type inference

F# basic
types

Named types

Conclusion

Appendix

Lists are so important that they even get their own special syntax, called **list comprehensions**, to simplify their creation and manipulation.

List comprehensions are substantially a way to map, filter, and cross lists easily.

Fold is excluded, and must be used for aggregate operations.
